Project No. 0305-5300688

OCTOBER 2003

EXECUTIVE SUMMARY

EBA Engineering Consultants Ltd. (EBA) was retained by Alberta Transportation, care of Brown and Associates Planning Group, to conduct a hydrogeological assessment of the proposed Spy Hill Lands gravel mining operation located at 33-025-2 W5M and the northern half of Section 28. The objective of the hydrogeological assessment is to determine whether the Spy Hill Lands Development Project will present any risk to the existing water wells in the vicinity of the mining operation, and to determine if the mining will affect the surface water bodies west of the site.

The scope of work included:

- reviewing available published geologic and hydrogeologic reports, to gain an understanding of the geologic and hydrogeological conditions in the general vicinity of site;
- collecting information from published hydrogeologic reports pertaining to surface water, water chemistry, water availability and local aquifers, as available;
- reviewing the Alberta Environment - Groundwater Information Centre (AE-GIC) water well database for information pertaining to nearby water well users within a 3 km radius;
- conducting a site visit to the gravel pits east of the proposed site location to “ground truth” geological and hydrogeological information; and
- preparation of a water balance for the site under the present conditions (undeveloped), and to identify potential changes to groundwater recharge under operating conditions.

Two distinct water-bearing units (i.e., aquifers) have been identified using information in the water well database, and various literary sources. They consist of a Tertiary Gravel unit and the bedrock Paskapoo Formation. The proposed Spy Hill aggregate operation will extract gravels from the Tertiary Gravel unit. The gravels at the site appear to be unsaturated; within the watershed, the gravel makes up an intermittent and largely unused aquifer. The extraction of the gravel for the proposed Spy Hill Land Development should have a minimal impact on portions of the gravel unit that do contain water. Extraction of the gravel is anticipated to minimally increase recharge to the underlying Paskapoo Aquifer.

The surface water is at a higher elevation than the water table in the underlying gravel; surface water bodies to the west (ponded on low permeability surface soils) should not be affected by the development. To the northeast, discharge to West Nose Creek should not be reduced. In addition, there should be no impact on the upper (gravel) aquifer. Recharge to any saturated portions of the gravel (and hence potential discharge to West Nose Creek) should not be affected. Recharge to the deeper bedrock (Paskapoo) aquifer should increase; there should be no negative impact on that aquifer. There is no apparent potential for an impact on domestic groundwater supplies resulting from the gravel extraction.

1.0 INTRODUCTION

EBA Engineering Consultants Ltd. (EBA) was retained by Brown and Associates Planning Group to conduct a hydrogeological assessment of the proposed Spy Hill Lands gravel mining operation, located at 33-025-02 W5M and the northern half of Section 28-025-02 W5M. The objective of the hydrogeological assessment is to determine whether the Spy Hill Lands Development Project will present a risk to the existing water wells in the vicinity of the mining operation, and to determine if the mining will affect the surface water bodies west of the site.

The scope of work included:

- reviewing available published geologic and hydrogeologic reports, to gain an understanding of the geologic and hydrogeological conditions in the general vicinity of site;
- collecting information from published hydrogeologic reports pertaining to surface water, water chemistry, water availability and local aquifers, as available;
- reviewing the Alberta Environment - Groundwater Information Centre (AE-GIC) water well database for information pertaining to nearby water well users, within a 3 km radius, whose water supply may be potentially affected;
- conducting a site visit to the gravel pits east of the proposed site location to “ground truth” geological and hydrogeological information; and
- preparation of a water balance for the site under the present conditions (undeveloped), and under operating conditions to identify potential changes to groundwater recharge.

The results of this work are described in Sections 3.0 to 5.0. Section 3.0 describes the geological and hydrogeological setting of the proposed aggregate operation. Section 4.0 and Section 5.0 describe groundwater users within the watershed boundary and the long-term water supply potential for the area, respectively.

This report was prepared based on data collected by EBA and by information reported by third parties. It was prepared under EBA’s Environmental Report – General Conditions for conducting Environmental work as presented in Appendix A.

2.0 SITE DESCRIPTION AND OPERATIONS

The Spy Hill Lands Development Project is located within the City of Calgary, adjacent to the northwest boundaries of the City (Figure 1). Full urban servicing and urban development has not yet occurred in this area. The area contains several aggregate operations, and institutional land use.

The proposed mining area includes the majority of Section 33 and the north half of Section 28 of 025-02 W5M (Figure 2). Based on data taken from on-site drill testing and preliminary assumptions about setback areas, the proposed mining area encompasses a gross area of six quarter sections. These quarter sections contain approximately 130 million tonnes of gravel.

It is understood that the extraction of the gravel will take place in six phases. Initially, the overburden will be removed and stockpiled, however, as the project progresses the overburden materials will be placed directly into previously mined areas prior to the cessation of a phase. The average depth of overburden within the proposed mining area is 13.2 m. The average depth of gravel is approximately 19.3 m. Extraction operations at the site are estimated to remove gravel to an average depth of 32 m. Upon completion of each phase, the overburden will be replaced (Brown and Associates Planning Group and Russ Gerrish Consulting, February 2003.).

3.0 GEOLOGIC AND HYDROGEOLOGIC SETTING

The geologic and hydrogeologic setting of the area has been evaluated to establish potential aquifers beneath the site and the probable yield of these aquifers. Sections 3.1 to 3.4 discuss the geology, hydrogeology, groundwater quality and flow regime, respectively.

3.1 Geology

The sediments overlying the gravel deposits that are to be mined are classified as Quaternary deposits of glacial and glaciolacustrine origin. Moran (1986) describes the material as pebble loam till, silts and sands. The thickness of the till ranges from 2 m to 30 m. At the proposed mining site the overlying till is approximately 13.2 m thick.

The gravel underlying the Quaternary deposits (the material proposed for extraction) is fluvial and lacustrine in origin, from the Tertiary era. The Tertiary gravel caps the uplands at the site. The gravel consists of well-rounded pebbles and cobbles of quartzite, and limestone (Moran, 1986). The gravel is approximately 10 m to 30 m thick and the base of the gravel deposit is generally 1,220 m (4,000 ft) in elevation. The gravel deposits cover approximately 48 km² of the Spy Hill area and are orientated northwest to southeast. The gravel deposits are shown in geological maps as not being continuous

throughout the Spy Hill Area. Figure 3 shows a plan view of the approximate extent of the gravel deposits at the site, although any lateral breaks in the deposits are small.

The Tertiary sediments are underlain by bedrock of the Paskapoo Formation. Hamilton et al. (1998) describes this formation as a grey to greenish grey, thick-bedded, calcareous, cherty sandstone; grey and green siltstone and mudstone; and minor conglomerates, thin limestone, coal and tuff beds of non-marine origin. This formation is believed to have been deposited on the floodplain east of the foothills. The sandstone beds of the Paskapoo Formation are of variable thickness, lens shaped, and are interbedded with dark, dense shale layers. Thin bentonitic shales and bentonite layers are also present and are the product of former volcanic activity. The thickness of the Paskapoo Formation is unknown at the site because historical drilling records did not extend into the bedrock. This formation may extend to a thickness of 600 m in the Calgary region (Osborn and Rajewicz, 1998).

The proposed mining site is located east of the eastern limit of structural deformation in the Rocky Mountain Foothills and thus the strata beneath the site are expected to be relatively flat lying. The lithology noted in water well logs, as found on the Alberta Environment water well database, indicate that stratigraphy is generally consistent throughout the proposed mining area.

3.2 Hydrogeology

The primary aquifers in the site area include the gravels and the sandstone layers of the Paskapoo Formation. For the purpose of this report, it is assumed that the thickness of the water bearing units represents the thickness of the aquifers.

3.2.1 Tertiary Gravel

Because the gravels have a limited thickness and lateral extent, the Tertiary gravel is expected to have a low groundwater yield. However, Ozoray and Barnes (1977) estimate that the gravel aquifer could form an aquifer that would yield an expected groundwater potential between 33 m³/day and 65 m³/day (5 to 10 Igpm). The maximum groundwater yield is representative of well-sorted sand and gravel deposits.

Wells completed within the silty sands and gravels record groundwater yields between 33 m³/day to 98 m³/day (5 to 15 Igpm) based on preliminary pump tests conducted after the wells were installed.

There have been no groundwater wells completed in the Tertiary gravel at the site. During a preliminary geotechnical investigation, 156 boreholes were advanced to define the depth and thickness of the gravel deposits and the depth to the water table. The maximum depth of the boreholes completed during this investigation was 21.3 m. Based on information provided by the client, three of the 156 boreholes intersected the water

table. The gravel deposits at the site appear to be unsaturated, and therefore are not considered to be an adequate aquifer for groundwater consumption.

3.2.2. Paskapoo Aquifer

The Paskapoo Aquifer in the Calgary area is described as a confined aquifer and is considered to be the interbedded sandstone layers of the Paskapoo Formation. Water wells completed in the Paskapoo Aquifer are expected to yield approximately 33 m³/day to 164 m³/day (5 to 25 Igpm) (Ozoray and Barnes, 1977). However, Meyboom (1961) anticipates that a water well that is developed in one or more of the sandstone aquifers could produce 6.5 m³/day to 26 m³/day (1 to 4 Igpm).

The primary lithologies of the water production interval for wells within a 1 km radius of the proposed mining site are predominantly shale and sandstone intervals of the Paskapoo Formation. The Paskapoo Aquifer has a water potential between 6.5 m³/day and 131 m³/day (1 to 20 Igpm) based on preliminary pump tests conducted after the wells were installed (Ozoray and Barnes, 1977).

3.3 Water Quality

Groundwater analyses from wells installed into the surficial deposits indicate the groundwater is generally chemically hard and high in dissolved iron. As water infiltrates into the ground it dissolves soluble materials. The most soluble minerals are dissolved first and as time progresses the less soluble materials come into solution (Ozoray and Barnes, 1978). Groundwater from the surficial aquifers can have a chemical hardness of greater than 200 mg/L and a total dissolved solids (TDS) concentration greater than 500 mg/L. Water from wells completed in the gravels does not have a dominant cation, but the water is mainly bicarbonate sulphate type (Agriculture and Agri-Foods Canada, 2002).

The Paskapoo Formation is dominated by a sodium-bicarbonate or sodium-sulphate type waters. The TDS concentrations in the Paskapoo Formation range from less than 500 mg/L to more than 3,000 mg/L. As depth increases, the TDS concentration increases (Agriculture and Agri-Foods Canada, 2002).

3.4 Flow Regime

The watershed area used for this study is shown on Figure 4. The southwest boundary is a surface water drainage divide that runs roughly northwest to southeast along the height-of-land (Ozoray and Barnes, 1978), the northern boundary is the Bigspring Creek, and the northeast boundary is West Nose Creek. The watershed area is divided into recharge and discharge areas, based on the assumptions that recharge coincides with topographic high areas, and discharge coincides with topographically low areas

(Domenico and Schwartz, 1990). The boundary between the recharge and discharge area is at approximately the 1,257 m topographic contour.

Above 1,257 m elevation in the southwest portion of the watershed, in the recharge area, surface water bodies comprise lakes, ponds, dugouts, sloughs and intermittent lakes ranging in area from 100 m² to 25,000 m². These surface water reside on the glacial and glaciolacustrine till layer. Below 1,257 m, in the discharge area, there are several northeastern-trending creeks that drain into West Nose Creek. The recharge area in the watershed area makes up 53,463,554 m².

The surface water to the west appears to be the result of precipitation ponding on low permeability surface soils. The surface water is at a significantly higher elevation than the water table in the underlying gravel (where a portion of the gravel is actually saturated). There is therefore little or no relationship between the surface water and the gravel unit (with the exception of some recharge to the gravel). Removal of the gravel would therefore not impact the surface water to the west.

On May 28, 2003, EBA conducted a site visit to the proposed Spy Hill Development location and to the gravel pits at a comparable elevation east of the proposed location. EBA observed pooled water at the bottom of the gravel pits, which the client attributed to remnant snow melt. EBA did not observe any groundwater seepage on the exposed walls of the gravel pits. This suggests that the groundwater surface does not intersect the pit bottom at this elevation. This is consistent with the previous geotechnical assessment of the site. The proposed development would be of a comparable depth. Dewatering of the pit should not be required, meaning that the local water table will not be drawn down.

4.0 REGIONAL WATER USAGE

The Alberta Environment – Groundwater Information Centre (AE-GIC) was reviewed for records of water wells located within the watershed. There are approximately 722 water wells in the area for domestic use in the watershed. The AE-GIC water well database indicates that there is one domestic well installed at the proposed Spy Hill Land Development site at SW 33-025-02 W5M. It is assumed that the well is no longer in use as the current landowner has no knowledge of the water well.

Water wells within the watershed boundary are summarised on Table 1. The following table summarises the classification of the wells in the database.

Table A
Water Wells Within the Watershed

	Domestic	Industrial	Stock	Unknown	Multiple Classifications	Total
Within the watershed.	648	5	19	25	25	722
Wells completed in the Gravels.	12	0	0	1	0	13
Wells completed in the Paskapoo Aquifer.	636	5	19	24	25	709

Table B summarises the number of wells completed in gravel; Figure 5 shows (by section) the location of these wells.

Table B
Water Wells Completed in the Gravel Aquifer

Radius	Domestic	Industrial	Investigative	Municipal	Stock	Unknown	Multiple Classifications	Total
Within the watershed	12	0	0	0	0	1	0	13

Three of the thirteen water wells completed in a gravel aquifer are not considered to be completed in the Tertiary gravel unit, based on their elevation and well completion depths. Therefore, there are 10 known wells completed in the Tertiary gravels in the watershed.

The water well data supports the regional hydrogeological information (Section 3.2). The gravel deposits do not form a significant local or regional aquifer.

5.0 WATER BALANCE

5.1 Basin Yield

Percolation recharges the soil, ultimately resulting in groundwater replenishment. Recharge to the Paskapoo Aquifer is considered in the water balance, as recharge to this aquifer is anticipated to change throughout the duration of the proposed aggregate operation. This prediction is based on the assumption that the Paskapoo Aquifer is recharged by precipitation (through vertical migration from the gravel deposits) and possibly by Nose Creek. Recharge to the gravel is not considered, as the gravel is either unsaturated (as appears to be the case in the site area), or does not form a significant aquifer.

To assess the current recharge and long term effects of aggregate extraction on the Paskapoo Aquifer a water balance was used. A water balance is a mathematical technique for keeping track of the water input to storage, water outputs to the atmosphere and for characterising the active features at the ground surface that influence the percolation of water into the soil (e.g., surface runoff, evapotranspiration and infiltration). The water balance described in this section has been compiled using the method described by McBean et al. (1995).

For the calculation of the water balance it is assumed that:

- 1) The Paskapoo aquifer extends throughout the watershed area. This was confirmed by looking at various water well reports to confirm the extent of the gravel aquifer.
- 2) Recharge from the various rivers and creeks within the watershed boundary was not considered.
- 3) All recharge percolates downwards and into the Paskapoo Aquifer.
- 4) Mining will remove all of the Tertiary gravel (to the bedrock).

Precipitation and daily mean temperatures for weather station at the University of Calgary was used to estimate the water balance for the site. The mean precipitation and daily mean temperatures were recorded from 1964 to 1990.

Figure 6 shows the water balance (calculated percolation and actual evapotranspiration) estimated for the watershed. The process used to generate this figure is summarised on Table 2.

The annual recharge per unit area (AR1) is calculated by summing the difference between actual evapotranspiration (AET) from percolation (PERC) for those months with a net surplus of water ($PERC > AET$) and subtracting AET for months of water deficit ($AET < 0$). The total annual recharge is estimated at approximately 95.87 mm per unit area.

5.2 Recharge and Discharge Areas

The recharge and discharge areas are shown on Figure 4. It is assumed that recharge coincides with topographic high areas and discharge coincides with topographically low areas. The entire area of the aggregate operations could be assumed to be a recharge area, as the work to date has shown the gravel to be unsaturated. Nonetheless, as a conservative estimate, the area of the site where the original ground is below 1,257 m (4,124 ft) (the site discharge area as shown on Figure 4) was not included in the calculated recharge area for each phase of the aggregate operation. The recharge area for

each phase of the aggregate operation and the total recharge area for the watershed basin are tabulated below.

Development and Watershed Recharge and Discharge

Aquifer	Total Area of Recharge (m ²)	Volume of Recharge (m ³)	Total Area
Phase 1	652,570	62,503	652,570
Phase 2	301,467	28,874	317,613
Phase 3	267,478	25,619	282,690
Phase 4	139,237	13,336	350,358
Phase 5	277,477	26,576	688,174
Phase 6	856,568	82,042	1,113,268
Overall Watershed	53,463,554	238,950	130,729,307

The recharge area of the Paskapoo aquifer within the watershed is estimated to be approximately 53,463,554 m². The volume of recharge prior to gravel extraction within the watershed was calculated by calculating the area of recharge within the watershed area and multiplying the area by the annual recharge value. The volume of recharge to the Paskapoo Aquifer prior to gravel excavation is approximately 238,950 m³/year.

5.3 Impacts of Gravel Extraction

Assuming that (as planned) each phase of the development will be reclaimed (overburden replaced) upon completion of a phase, or while work proceeds, no more than the approximate total area of a single phase will be unreclaimed at any time. As the gravel is extracted and the vegetation at the site is removed, precipitation will fall to the floor of the gravel pit and percolate downward into the Paskapoo Aquifer. As a result of a reduction of vegetation at the site, evapotranspiration will decrease therefore increasing the amount of recharge to the Paskapoo Aquifer. The maximum increase in recharge would occur if 100% of Phase 6 were open and unreclaimed at some point in time.

After reclamation, the existing surface (glacial and glaciolacustrine) material will be replaced and the area re-vegetated. At that point the recharge rate to the Paskapoo Aquifer should be similar to the present pre-disturbance condition. Recharge will tend to be directly into the Paskapoo Aquifer (as the intervening gravel unit will no longer be present), resulting in a long-term increase in recharge to that aquifer. The increase in recharge is difficult to quantify and should be slight.

Based on the available data it is anticipated that extraction of the aggregates will not negatively affect groundwater supplies. The gravel deposits at the site are unsaturated, and the underlying bedrock (Paskapoo) aquifer should receive slightly increased recharge.

5.4 Water Quality

The groundwater quality within the gravel will not be affected by the removal of the aggregates because the gravel in the site area appears to be unsaturated. Operational activities such as use of chemical agents for dust control, spills, fuel or chemical storage, have a potential to affect the underlying Paskapoo Aquifer. The Paskapoo is a large regional aquifer, and should not be significantly affected by development of the aggregate operation. The aquifer is an important resource, however, and to limit the possibility of adverse impacts to the water quality the following is recommended:

- quantities of calcium chloride or other chemical agents for dust control should be minimised, to the extent practical;
- chemicals or fuel stored onsite should be placed in appropriate above ground storage containers (with secondary containment); and
- a spill response plan should be prepared.

6.0 CONCLUSION

The proposed mining area includes the majority of Section 33 and the north half of Section 28 of 025-02 W5M (Figure 2). It is understood that the extraction of the gravel will take place in six phases. The depth to the top of the gravel is approximately 13.2 m. Extraction operations at the site are estimated to remove gravel to an average depth of approximately 32 m. The base of the pit should not intercept the water table.

Two distinct water-bearing units (i.e., aquifers) have been identified using information in the water well database, and various literary sources. The Tertiary gravels at the site appear to be unsaturated; within the watershed, the gravel makes up an intermittent and largely unused aquifer. The extraction of the gravel for the proposed Spy Hill Land Development should have a minimal impact on portions of the gravel unit that do contain water. Extraction of the gravel is anticipated to minimally increase recharge to the underlying Paskapoo Aquifer.

The surface water is at a higher elevation than the water table in the underlying gravel; surface water bodies to the west (ponded on low permeability surface soils) should not be affected by the development. To the northeast, discharge to West Nose Creek should not be reduced. In addition, there should be no impact on the upper (gravel) aquifer. Recharge to any saturated portions of the gravel (and hence potential discharge to West Nose Creek) should not be affected. Recharge to the deeper bedrock (Paskapoo) aquifer should increase; there should be no negative impact on that aquifer. There is no apparent potential for an impact on domestic groundwater supplies resulting from the gravel extraction.

7.0 LIMITATIONS OF LIABILITY

Conclusions and recommendations presented herein are based on an authorised groundwater assessment as described in Section 1.0. This report has been prepared for the use of Alberta Transportation and their approved agents for the specific application described above. It has been prepared in accordance with generally accepted environmental engineering practices. No other warranty is made, either express or implied. EBA's Environmental Report – General Conditions under which this work was performed are provided in Appendix A.

8.0 CLOSURE

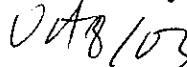

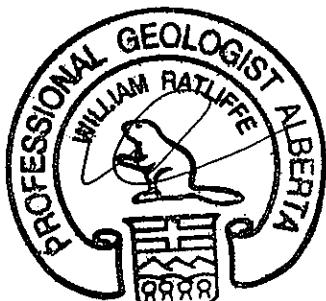

We trust this information meets your present requirements. Should you have any questions, please contact Ms. Taschuk, Ms. Messing or Mr. Ratliffe at our Calgary Riverbend office.

P (inches of water)	P	P = PERC+AET+DST+r/o	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.01	Calculation Check

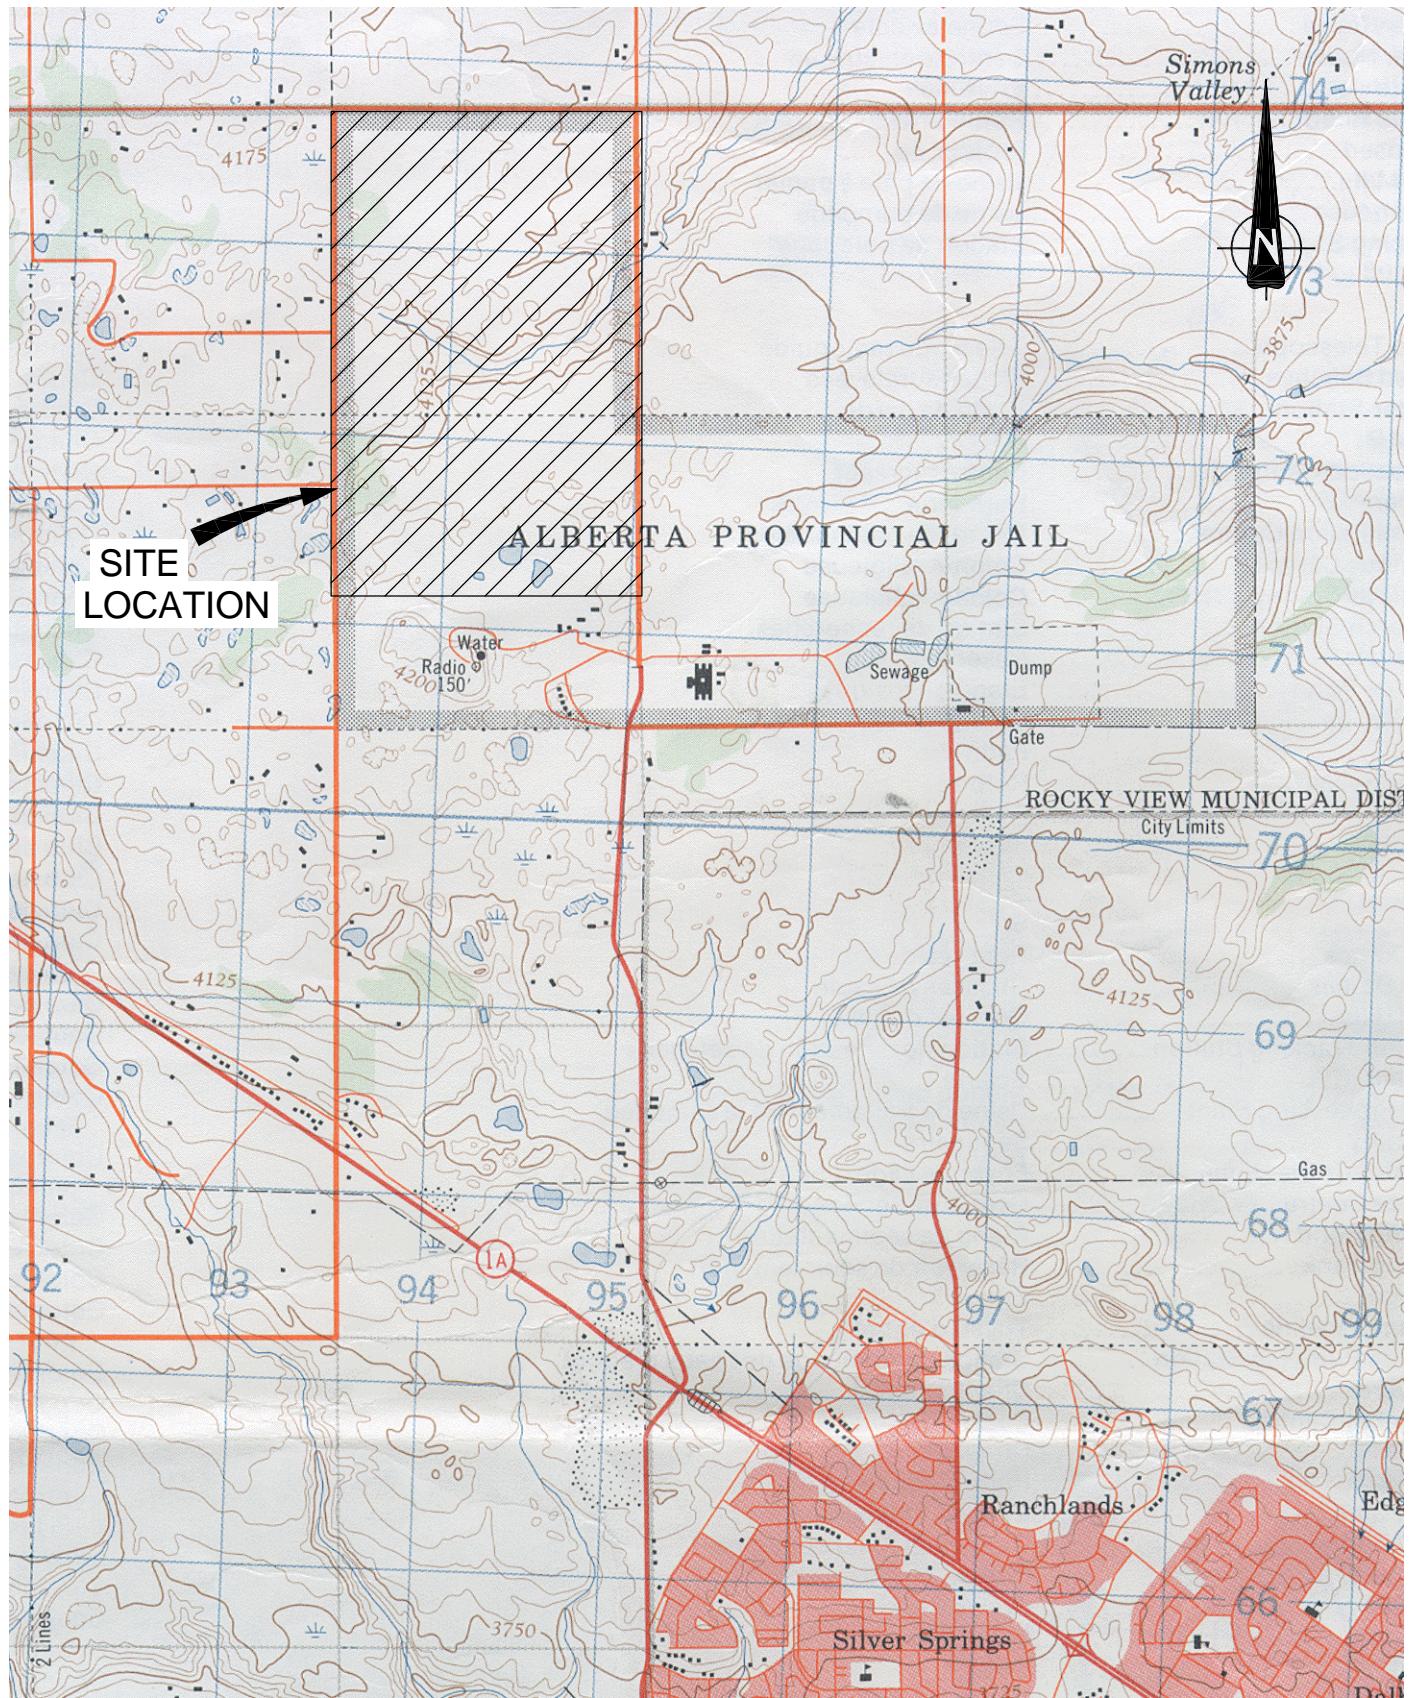

Notes: Runoff Coefficient, C r/o = 0.95 for winter months ($T < 0^{\circ}\text{C}$). For the growing season, C r/o = 0.15 for silt and clay loam in aspen parkland.

The field capacity was estimated at 8 inches for the montly soil moisture storage by McBean et al. (1995). A conservative field capaicty of 5 inches was used in the water balance.

ENVIRONMENTAL REPORT - GENERAL CONDITIONS

EBA Engineering Consultants Ltd. (EBA)

ENVIRONMENTAL REPORT – GENERAL CONDITIONS

This report incorporates and is subject to these “General Conditions”.

1.0 USE OF REPORT

This report pertains to a specific site, a specific development, and a specific scope of work. It is not applicable to any other sites, nor should it be relied upon for types of development other than those to which it refers. Any variation from the site or proposed development would necessitate a supplementary investigation and assessment.

This report and the assessments and recommendations contained in it are intended for the sole use of EBA’s client. EBA does not accept any responsibility for the accuracy of any of the data, the analysis or the recommendations contained or referenced in the report when the report is used or relied upon by any party other than EBA’s client unless otherwise authorized in writing by EBA. Any unauthorized use of the report is at the sole risk of the user.

This report is subject to copyright and shall not be reproduced either wholly or in part without the prior, written permission of EBA. Additional copies of the report, if required, may be obtained upon request.

2.0 LIMITATIONS OF REPORT

This report is based solely on the conditions which existed on site at the time of EBA’s investigation. The client, and any other parties using this report with the express written consent of the client and EBA, acknowledge that conditions affecting the environmental assessment of the site can vary with time and that the conclusions and recommendations set out in this report are time sensitive.

The client, and any other party using this report with the express written consent of the client and EBA, also acknowledge that the conclusions and recommendations set out in this report are based on limited observations and testing on the subject site and that conditions may vary across the site which, in turn, could affect the conclusions and recommendations made.

The client acknowledges that EBA is neither qualified to, nor is it making, any recommendations with respect to the purchase, sale, investment or development of the property, the decisions on which are the sole responsibility of the client.

2.1 Information Provided to EBA by Others

During the performance of the work and the preparation of this report, EBA may have relied on information provided by persons other than the client. While EBA endeavours to verify the accuracy of such information when instructed to do so by the client, EBA accepts no responsibility for the accuracy or the reliability of such information which may affect the report.

3.0 LIMITATION OF LIABILITY

The client recognizes that property containing contaminants and hazardous wastes creates a high risk of claims brought by third parties arising out of the presence of those materials. In consideration of these risks, and in consideration of EBA providing the services requested, the client agrees that EBA’s liability to the client, with respect to any issues relating to contaminants or other hazardous wastes located on the subject site shall be limited as follows:

- (1) With respect to any claims brought against EBA by the client arising out of the provision or failure to provide services hereunder shall be limited to the amount of fees paid by the client to EBA under this Agreement, whether the action is based on breach of contract or tort;
- (2) With respect to claims brought by third parties arising out of the presence of contaminants or hazardous wastes on the subject site, the client agrees to indemnify, defend and hold harmless EBA from and against any and all claim or claims, action or actions, demands, damages, penalties, fines, losses, costs and expenses of every nature and kind whatsoever, including solicitor-client costs, arising or alleged to arise either in whole or part out of services provided by EBA, whether the claim be brought against EBA for breach of contract or tort.

EBA Engineering Consultants Ltd. (EBA)

ENVIRONMENTAL REPORT – GENERAL CONDITIONS

4.0 JOB SITE SAFETY

EBA is only responsible for the activities of its employees on the job site and is not responsible for the supervision of any other persons whatsoever. The presence of EBA personnel on site shall not be construed in any way to relieve the client or any other persons on site from their responsibility for job site safety.

5.0 DISCLOSURE OF INFORMATION BY CLIENT

The client agrees to fully cooperate with EBA with respect to the provision of all available information on the past, present, and proposed conditions on the site, including historical information respecting the use of the site. The client acknowledges that in order for EBA to properly provide the service, EBA is relying upon the full disclosure and accuracy of any such information.

6.0 STANDARD OF CARE

Services performed by EBA for this report have been conducted in a manner consistent with the level of skill ordinarily exercised by members of the profession currently practicing under similar conditions in the jurisdiction in which the services are provided. Engineering judgement has been applied in developing the conclusions and/or recommendations provided in this report. No warranty or guarantee, express or implied, is made concerning the test results, comments, recommendations, or any other portion of this report.

7.0 EMERGENCY PROCEDURES

The client undertakes to inform EBA of all hazardous conditions, or possible hazardous conditions which are known to it. The client recognizes that the activities of EBA may uncover previously unknown hazardous materials or conditions and that such discovery may result in the necessity to undertake emergency procedures to protect EBA employees, other persons and the environment. These procedures may involve additional costs outside of any budgets previously agreed upon. The client agrees to pay EBA for any expenses incurred as a result of such discoveries and to compensate EBA through payment of additional fees and expenses for time spent by EBA to deal with the consequences of such discoveries.

8.0 NOTIFICATION OF AUTHORITIES

The client acknowledges that in certain instances the discovery of hazardous substances or conditions and materials may require that regulatory agencies and other persons be informed and the client agrees that notification to such bodies or persons as required may be done by EBA in its reasonably exercised discretion.

9.0 OWNERSHIP OF INSTRUMENTS OF SERVICE

The client acknowledges that all reports, plans, and data generated by EBA during the performance of the work and other documents prepared by EBA are considered its professional work product and shall remain the copyright property of EBA.

10.0 ALTERNATE REPORT FORMAT

Where EBA submits both electronic file and hard copy versions of reports, drawings and other project-related documents and deliverables (collectively termed EBA's instruments of professional service), the Client agrees that only the signed and sealed hard copy versions shall be considered final and legally binding. The hard copy versions submitted by EBA shall be the original documents for record and working purposes, and, in the event of a dispute or discrepancies, the hard copy versions shall govern over the electronic versions. Furthermore, the Client agrees and waives all future right of dispute that the original hard copy signed version archived by EBA shall be deemed to be the overall original for the Project.

The Client agrees that both electronic file and hard copy versions of EBA's instruments of professional service shall not, under any circumstances, no matter who owns or uses them, be altered by any party except EBA. The Client warrants that EBA's instruments of professional service will be used only and exactly as submitted by EBA.

The Client recognizes and agrees that electronic files submitted by EBA have been prepared and submitted using specific software and hardware systems. EBA makes no representation about the compatibility of these files with the Client's current or future software and hardware systems.
